

EXP:12 MULTIPLY TWO 16-BIT BINARY NUMBER

The screenshot displays the Keil uVision IDE interface. The main window shows the source code for a C program named `embxp12.c`. The code defines two unsigned integers, `num1` and `num2`, with values 3000 and 2000 respectively. It then calculates the product of these two numbers and stores the result in a variable named `result`. The program includes a `main` function that prints the result and a `while` loop that runs indefinitely.

The **Registers** window on the left shows the state of the processor registers. The **Watch** window on the right displays the values of the variables `num1`, `num2`, and `result`. The `result` variable is shown with a value of 0x00000000, which is the hexadecimal representation of 0.

```
1 #include <reg51.h>
2
3 unsigned int num1 = 3000;
4 unsigned int num2 = 2000;
5
6 unsigned long result;
7
8 void main()
9 {
10     result = (unsigned long)num1 * num2;
11     while(1);
12 }
13
```

Name	Value	Type
num 1	<cannot evaluate>	uchar
num 2	<cannot evaluate>	uchar
result	0x00000000	ulong
